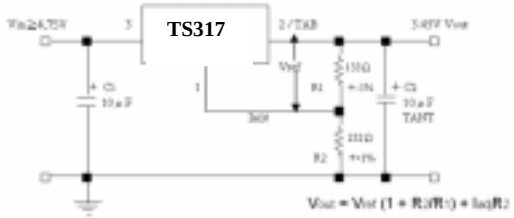
STANDARD APPLICATION



* = Cin is required if regulator is located an appreciable distance from power supply filter.
** = Co is not needed for stability, however it does improve transient response.
$V_{out} = 1.25\ V\ (1 + R_2 / R_1) + I_{Adj}\ R_2$
Since I_{Adj} is controlled to less than 100 μA, the error associated with this term is negligible in most applications

BASIC CIRCUIT OPERATION

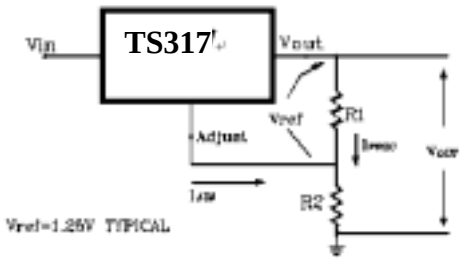
The TS317 is a 3-terminal floating regulator. In operation, the TS317 develops and maintains a nominal 1.25 volt reference (V_{ref}) between its output and adjustment terminals. This reference voltage is converted to a programming current (I_{PROG}) by R_1 (see Figure 17), and this constant current flows through R_2 to ground. The regulated output voltage is given by:

$V_{out} = Vref\ (1+\ R_2 / R_1\ ) + I_{Adj}\ R_2$

Since the current from the adjustment terminal (I_{adj}) represents an error term in the equation, the TS317 was designed to control I_{adj} to less than 100 μA and keep it constant. To do this, all quiescent operating current is returned to the output terminal. This imposes the requirement for a minimum load current. If the load current is less than this minimum, the output voltage will rise.

Since the TS317 is a floating regulator, it is only the voltage differential across the circuit which is important to performance, and operation at high voltages with respect to ground is possible.

FIGURE 17 -BASIC CIRCUIT CONFIGURATION



output increased. A 10μF capacitor should improve ripple capacitance (C_O) in the form of a 1 μF tantalum or 25 μF aluminum electrolytic capacitor on the output swamps this effect and insures stability.

PROTECTION DIODES

When external capacitors are used with any I.C. regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator.

Figure 18 shows the TS317 with the recommended protection diodes for output voltages in excess of 25 V or high capacitance values (C_O > 25 μF, C_{ADJ} > 10μF). Diode D_1 prevents C_O from discharging thru the I.C. during an input short circuit. Diode D_2 protects against capacitor C_{ADJ} discharging through the I.C. during an output short circuit. The combination of diodes D_1 and D_2 prevents C_{ADJ} from discharging through the I.C. during an input short circuit.

EXTERNAL CAPACITORS

A 0.1μF disc or 1μF tantalum input bypass capacitor (C_{in}) is recommended to reduce the sensitivity to input line impedance.

The adjustment terminal may be bypassed to ground to improve ripple rejection. This capacitor (C_{ADJ}) prevents ripple from being amplified as the output voltage is rejection about 15dB at 120 H_Z in a 10 volt application.

Although the TS317 is stable with no output capacitance, like any feedback circuit , certain values of external capacitance can cause excessive ringing. An

The TS317 is capable of providing extremely good load regulation, but a few precautions are needed to obtain maximum performance. For best performance, the programming resistor (R_1) should be connected as close to the regulator as possible to minimize line drops which effectively appear in series with the reference, thereby degrading regulation . The ground end of R_2 can be returned near the load ground to provide remote ground sensing and improve load regulation.
